**Keywords:** Colour, Murano Glass, Smalti, Trencadís, Preliminary Alteration Patterns.

1 **Introduction**

The traditional coloring agents commonly used for Murano glass are a limited number of metal ions which, by absorbing part of the incident light, give rise to a great diversity of colorations.

During the process of mixing, melting, forming and subsequent cooling of the piasters, they acquire various primary defects that alter their surface quality. These primary defects not only devalue their appearance but can also reduce their durability expectations as they are the source of new secondary anomalies that appear with the passage of time and exposure to the weather.

The objective of this research is to develop a procedure that allows grouping and ordering the various references of Murano glass available according to their apparent surface quality, so that artisans can select and use those references that, for the same color, have fewer primary defects. In order to favor this objective, the following inspection methodology, census and assessment of surface quality were proposed.

2 Methodology

An universe of 77 references and 2 pieces for each reference, have been digitized. To assess the visible surface quality of each sample on each face:
- an initial value of 10 has been granted to each face.
- for each face of each piece examined, a qualitative assessment of each defect has been made, giving a value of -1 if the said defect is generalized or 0 if it is punctual or non-existent.

3 Conclusions

About the references of Murano glass, the results are as follows:

<table>
<thead>
<tr>
<th>Quality</th>
<th>Brown</th>
<th>Violet</th>
<th>White</th>
<th>Blue</th>
<th>Green</th>
<th>Orange</th>
<th>Yellow</th>
<th>Red</th>
<th>Pink</th>
<th>Black</th>
<th>Grey</th>
</tr>
</thead>

</tbody>
</table>

Murano Smalti glass has been revealed as a material with a high amount of concurrent surface primary defects, defects that affect similarly to its two faces, although they predominate on its face (B). It can be concluded because most of the primary defects observed are inherent to the product as it is currently produced and few others are inherent to the face (B), which is in contact with the forming table. The results of this preliminary study, although they illustrate quite clearly the primary defects that this material suffers, should still be considered indicative, since several limiting causes must be considered:
- these are parts from references of a single manufacturer and have been voluntarily selected by the manufacturer itself to be a sample.
- these are cut pieces of larger piastras; In the reality of the work, this intermediate format is not used, but each tile is extracted, by fractionation, from any area of the piastra.
- the number of references and colors analyzed in each range is not equivalent.
