Key words: Vibrations of plates, Mid-frequencies, Uncertainty, Random excitation, Turbulent excitation.

Vibration uncertainty plays a major role in the dynamic behaviour of structures, especially in the mid- and high-frequency ranges. Such uncertainty can arise as a consequence of the uncertainty in the properties of the structure, such as the geometry, the material properties or the boundary conditions, and also from the uncertainty in the source mechanism. Common examples include defective contact areas between two structural components and turbulent flow in the vicinity of a structure.

This paper provides a method for computing the vibration response and its probability distribution for a plate subjected to random excitation over an extended area. The methodology relies on the image source method, which consists in representing successive wave reflections in a structure by means of a series of mirror sources. The spatial nature of such representation makes it appropriate for computing the response of finite structures in the mid- and high-frequency ranges.

The image source method [1, 2] provides the Green’s function between two points of the structure. The response to a spatially-extended excitation is obtained by taking advantage of the reciprocity of the Green’s function [3, 4]. The source is described using a statistical model of a spatially-extended random excitation, consisting in a superposition of random fields with different spatial scales. This allows to study of the uncertainty in the vibration response in connection with the statistical properties of the source, such as the spatial cross-correlation and the probability distribution. An application example will be given for a polygonal panel excited by a turbulent flow. The wall pressure is obtained using an unsteady time-domain computational fluid dynamic simulation and used as the vibration input in the image source method. The statistical properties of the wall pressure are...
extracted and the relation with the probability distribution of the vibration response is discussed.

Fig. 1 shows a preliminary example of the influence of the spatial cross-correlation of the source on the probability distribution of the vibrations of a polygonal panel.
